ABSTRACT

A lead-zinc smelter and fertilizer complex at Trail, British Columbia discharge effluents into the Columbia River which flows across the Canada-United States border. Water quality monitoring conducted in 1977-79 showed elevated levels of metals and nutrients in the Columbia River downstream of the discharges. Decreases in the concentrations of metals discharged into the river were expected with the modernization of the smelting operations planned for the late 1970's through to the early 1990's.

The Selenastrum capricornutum Algal Assay Bottle Test was used to investigate the following:

1. Can metal concentrations in Columbia River water downstream of Trail inhibit algal growth?
2. When the effects of metals are reduced in the future, is there greater potential for algal growth downstream than upstream of Trail?

This report presents the algal assay results with accompanying data on the concentrations of chemicals and indigenous algae in the river water. A description of the field and laboratory methods used in the study is included.

RESUME

Une fonderie de plomb et de zinc ainsi qu'un complexe de fertilisants sont situés à Trail, en Colombie-Britannique; ils déversent leurs eaux usées dans la rivière Columbia, qui traverse ensuite la frontière entre le Canada et les Etats-Unis. De 1977 à 1979, un programme de surveillance continue de la qualité des eaux a mis en évidence des concentrations accrues de métaux et de nutriments dans la rivière Columbia en aval des usines. La modernisation de la fonderie a débuté à la fin des années 70 et doit se terminer au début des années 90; suite à cette modernisation, on devrait observer une diminution de la concentration des métaux dans les eaux usées.

Un test en bouteille avec l'algue Selenastrum capricornutum a été utilisé pour répondre aux questions suivantes:

1. Les concentrations de métaux dans l'eau de la rivière Columbia en aval de Trail peuvent-elles inhiber la croissance des algues?
2. Quand l'influence des métaux aura été réduite lors des années subséquentes, y a-t-il possibilité plus grande en aval qu'en amont pour la croissance des algues?

Le présent rapport renferme les résultats des tests avec l'algue Selenastrum capricornutum ainsi que des données pertinentes sur les concentrations de diverses substances chimiques et d'algues indigènes dans l'eau de la rivière. Une description des méthodes utilisées sur le terrain et au laboratoire est incluse.

ACKNOWLEDGEMENTS

We would like to acknowledge the encouragement and support of Dr. W.E. Erlebach, Chief of the Water Quality Branch, Inland Waters and Lands, Pacific and Yukon Region throughout all phases of this study.

We are especially grateful to M. Bolin and S.G. Yee for providing technical expertise and advice in conducting the algal assays and for the analysis of algal samples. We would like to thank F.T.S. Mah and personnel of the Analytical Services Division for precise analysis of water samples. This study would not have been possible without the capability of our regional Water Quality Laboratory to analyse water samples for metals and nutrients immediately upon receipt at the laboratory. We are especially grateful to P.A. Thomson and N. Wade for these analyses.

We thank Cominco Inc. for providing access to one of their discharge sewers for collection of water samples. We are grateful to Dr. A.L. Smith for the compilation, manipulation and graphic display of the data. We are indebted to M. Lamb, Water Quality Branch, Ottawa and D. Burroughs, formerly of Water Quality Branch, Ottawa for input, formatting and reformatting of the water chemistry data. We are very grateful to M.L. Haines for her typing and revisions of the report. The comments provided by the reviewers, Dr. L.M. Churchland, P.H. Whitfield and R.E. Kwiatkowski were appreciated.

I. INTRODUCTION

The Columbia is a major waterway which flows across the Canada-United States border near Trail, British Columbia into the State of Washington. Fifteen kilometres upstream of the international border a large lead-zinc smelter and fertilizer complex operated by Cominco Limited discharges effluent into the Columbia River.

Water quality monitoring conducted by Inland Waters and Lands in 1977-79 showed that elevated levels of metals and nutrients were intermittently present in the Columbia River downstream of Cominco (Sheehan and Lamb, in prep.). It was expected that the levels of metals in the river would decrease following modernization of the smelting operations planned by Cominco for the late 1970's through to the early 1990's.

Inland Waters and Lands and Environmental Protection were concerned that reductions in metal discharges, without accompanying reductions in nutrient discharges, could result in nuisance algal growth or blooms downstream of Trail. It was hypothesized that the elevated metal concentrations in the river may have been responsible for inhibiting algal growth in the past.

In response to these concerns, the following were investigated:

1. Can metal concentrations in Columbia River water downstream of Trail inhibit algal growth?
2. When the effects of metals are reduced in the future, is there greater potential for algal growth downstream than upstream of Trail?

The approach used to assess the present and predict the future algal growth potential of the river water was the Selenastrum capricornutum Printz Algal Assay Bottle Test (Miller et al., 1978). This laboratory algal assay measures the growth of an algal culture in sample water. To gain an understanding of indigenous algal flora present in the Columbia River, samples of Columbia River water were analysed for algal species composition and abundance.

This data report presents the results of eight algal assays conducted from 1980 to 1982 with supporting data on the concentrations of chemicals measured in the field and laboratory. The rationale for the use of the algal assay technique and its application to this study are presented. Also included is a detailed description of the field and laboratory methods used.

The results are arranged in three sections. Section A presents data associated directly with the algal assays. Sections B and C present additional data characterizing the aquatic quality of the river. Section B contains data on species composition and abundance of indigenous phytoplankton and periphyton of the Columbia River.

These samples were collected on early reconnaissance trips (1978-1979) and in conjunction with water samples for algal assays (1980-1982). Section C presents data on the concentrations of chemicals and the composition of phytoplankton in samples collected upstream of Birchbank at Kootenay River near its confluence with the Columbia River and at the Columbia River just downstream of Hugh Keenleyside Dam in an attempt to trace the source of elevated metal and phosphorus concentrations measured at Birchbank (the station upstream of Cominco discharges) in July 1980.

The interpretive report (in prep.) will present an analysis and discussion of the results of this study. There will be an analysis of the algal growth potential and limiting nutrients at stations upstream and downstream of Cominco effluents, an analysis of the effects of metal discharges on algal growth, and a prediction of future algal growth potential in the river when metal discharges are decreased. Also included will be an analysis of the effects of pre-assay laboratory preparation of sample water on the concentrations of chemicals in the water.

II. RATIONALE FOR THE SELECTION OF THE ALGAL ASSAY TEST FOR THIS STUDY

The approach selected to address the objectives of this study had to have the following capabilities:

1. the ability to predict algal growth in the future when metal levels in the river will be substantially decreased;
2. the ability to measure algal growth potential in river water during "worst case" conditions, that is, during random episodic peak metal discharges from Cominco;
3. the capability to contend with characteristics of the Columbia River in the Trail vicinity, such as;

    a) the short distance (15 km, approximately 5 hours travel time for a specific mass of water) from the discharge site to the international boundary which does not allow sufficient time for phytoplankton to reflect chemical changes in the water,

    b) the fluctuating water level in the river due to upstream dams on the Columbia and Kootenay Rivers which discourages the growth of periphytic algae. The major algal component in the river, therefore, is phytoplankton, which probably originates from upstream reservoirs.

A controlled experimental or bioassay approach using the Selenastrum capricornutum Printz Algal Assay Bottle Test was seen as a suitable

technique for meeting the study objectives under the conditions imposed by the study site. The algal assay bottle test has been used by various investigators to study (1) the algal growth potential of waters, (2) the identity of nutrients limiting algal growth, and (3) the presence of substances that are toxic or inhibitory to algal growth (Miller et al., 1974; Greene et al., 1975a; Miller et al., 1975; Gerhold, 1975; Gerhold and Otto, 1976; Miller et al., 1976; Parr and Smith, 1976; Greene et al., 1978; Davis and DeCosta, 1980; Grizzard et al., 1980; Dobolyi and Ördög, 1981; Olive and Higgins, 1981; Markee et al., 1982; Perry and Stanford, 1982; Ram and Plotkin, 1983; Turbak et al., 1986). Studies by Greene et al., (1975b) showed that algal growth potential predicted by the algal assay technique agreed favourably with indigenous phytoplankton standing stocks.

The algal assay bottle test was appropriate for this study because it allows for the containment of river water in the laboratory so that the algal growth response can be measured. An advantage of this technique is that the sample water can be manipulated to investigate factors affecting algal growth. With the addition of the chelating compound EDTA excess dissolved metals can be complexed to EDTA and made unavailable for algal uptake. Hence this would simulate future conditions when metals are present in lower concentrations in the river.

This technique also allowed for the simulation of "worst case" metal discharge conditions by the addition of effluent collected directly from Cominco sewers. The simulation was required because peak metal discharges were present in downstream waters at occasional and unpredictable times. When water collections were made it was not known if high metal levels were present in the downstream (Waneta) sample until the water was analysed at the laboratory. If the metals levels were considerably lower than those measured during previous intensive monitoring series (Sheehan and Lamb, in prep.), an appropriate volume of Cominco effluent could be added to some of the Waneta samples, so that the algal growth potential under high metal discharge conditions could be measured.

III. DESCRIPTION OF THE ALGAL ASSAY TEST AND ITS APPLICATION IN THIS STUDY

The Selenastrum capricornutum Printz Algal Assay Bottle test was developed by the U.S. Environmental Protection Agency and is described in detail in Miller et al. (1978).

For this test, the unicellular green alga, Selenastrum capricornutum, is grown in sample water under controlled laboratory conditions. When the culture ceases to increase in biomass, its final biomass is used as a measure of the algal growth potential in that particular water. Waters with higher concentrations of nutrients should result in greater biomass of S. capricornutum and hence have a greater growth potential.

The macronutrient limiting algal growth in water can be identified by growing the alga in water samples that have been spiked with the macronutrients, orthophosphate and nitrate. These two macronutrients are added individually to sample water. The final biomass of these "spiked" samples is compared to the final biomass of the control or unspiked sample. If, for example, greater growth is measured in the sample water spiked with orthophosphate, this indicates that orthophosphate is present in limited supply in the original sample water. Thus the availability of orthophosphate in the water is controlling the growth of algae. If greater growth results only when both macronutrients are added together this indicates that neither macronutrient, alone, is limiting the growth of algae.

When no increase in biomass (when compared to the biomass in the unspiked control sample) is evident with the addition of the macronutrients individually or together this indicates that some other factor is limiting algal growth. The growth-limiting factor could be the lack of a micronutrient or trace element that is required for algal growth. Alternatively, the growth could be limited by the presence of a substance that has a toxic or inhibitory effect on algal growth. The specific cause of the growth limitation can be narrowed down with further spikes to the water. For example, the water can be spiked with the chelating compound EDTA. EDTA acts as a complexing agent for metals and mediates the dissolved or biologically-available portion of trace metals in water (Miller et al., 1976). If greater growth results with the addition of EDTA this then indicates one of two possible conditions, either (1) trace metals are available to the algae in excessive concentrations and are therefore inhibiting the algal growth or (2) trace metals in the sample water are present but unavailable for algal uptake. An analysis of the concentrations of metals in the water will shed further light on which of the above two conditions is most likely.

The algal assays conducted on Columbia River water, generally, followed the experimental design described in Miller et al. (1978). The alga was grown in water samples collected upstream (Birchbank) and downstream (Waneta) of Cominco discharges to determine the effect of Cominco discharges on algal growth potential in the

water. Nutrient additions to these waters investigated the effect of Cominco discharges on limiting nutrients in the water. EDTA was added to ascertain if metals were affecting the growth of algae. This treatment also gave an indication of the algal growth potential of Waneta water when the growth-limiting or inhibitory effects, if any, of the metals are reduced in the future.

For some assays further spikes were added to test if metal deficiencies upstream of Cominco effluents may be limiting the growth of algae in the river. The effect of Cominco effluents on these deficiencies, if any, could then be ascertained. Note, if metals are not present in some form in the water the addition of EDTA would have no effect on metal availability. A spike of trace metals was added for some of the assays (August and September, 1982). A spike of iron alone was included as a treatment for most assays. Iron has been shown to limit the growth of S. capricornutum at some downstream Columbia River locations in the United States (Miller et al., 1976). Data on the concentrations of dissolved iron at Birchbank indicate low concentrations (1 to 2 µg Fe/L) (Sheehan and Lamb, in prep).

IV. STUDY SITES

Sampling sites are shown in Figure 1. For each algal assay, water samples were collected at Birchbank (NAQUADAT no. 00BC08NE0005) which is located upstream of Cominco discharges at Trail and at Waneta (NAQUADAT no. 00BC08NE0001) which is located downstream of these discharges.

On most sampling dates samples were collected from Cominco smelter's sewer #8 (NAQUADAT no. 20BC08NE0001) which discharges from the zinc roaster and sulphuric acid plant area to the Columbia River. This water was added to samples of Waneta water to simulate high Cominco metal discharge conditions at Waneta.

On September 17, 1980, water samples were also collected from the Pend d'Oreille River (NAQUADAT no. 00BC08NE0029) near its confluence with the Columbia. The Pend d'Oreille River is a major tributary of the Columbia River, contributing a significant input of water to the Columbia River, downsteam of the Waneta sampling station. It was considered important to determine the algal growth potential of this tributary to better predict the algal growth potential in downstream Columbia River water in the United States.

On August 11 and September 17, 1980 the following two locations upstream of Birchbank were sampled: Kootenay River near its confluence with the Columbia River and the Columbia River just

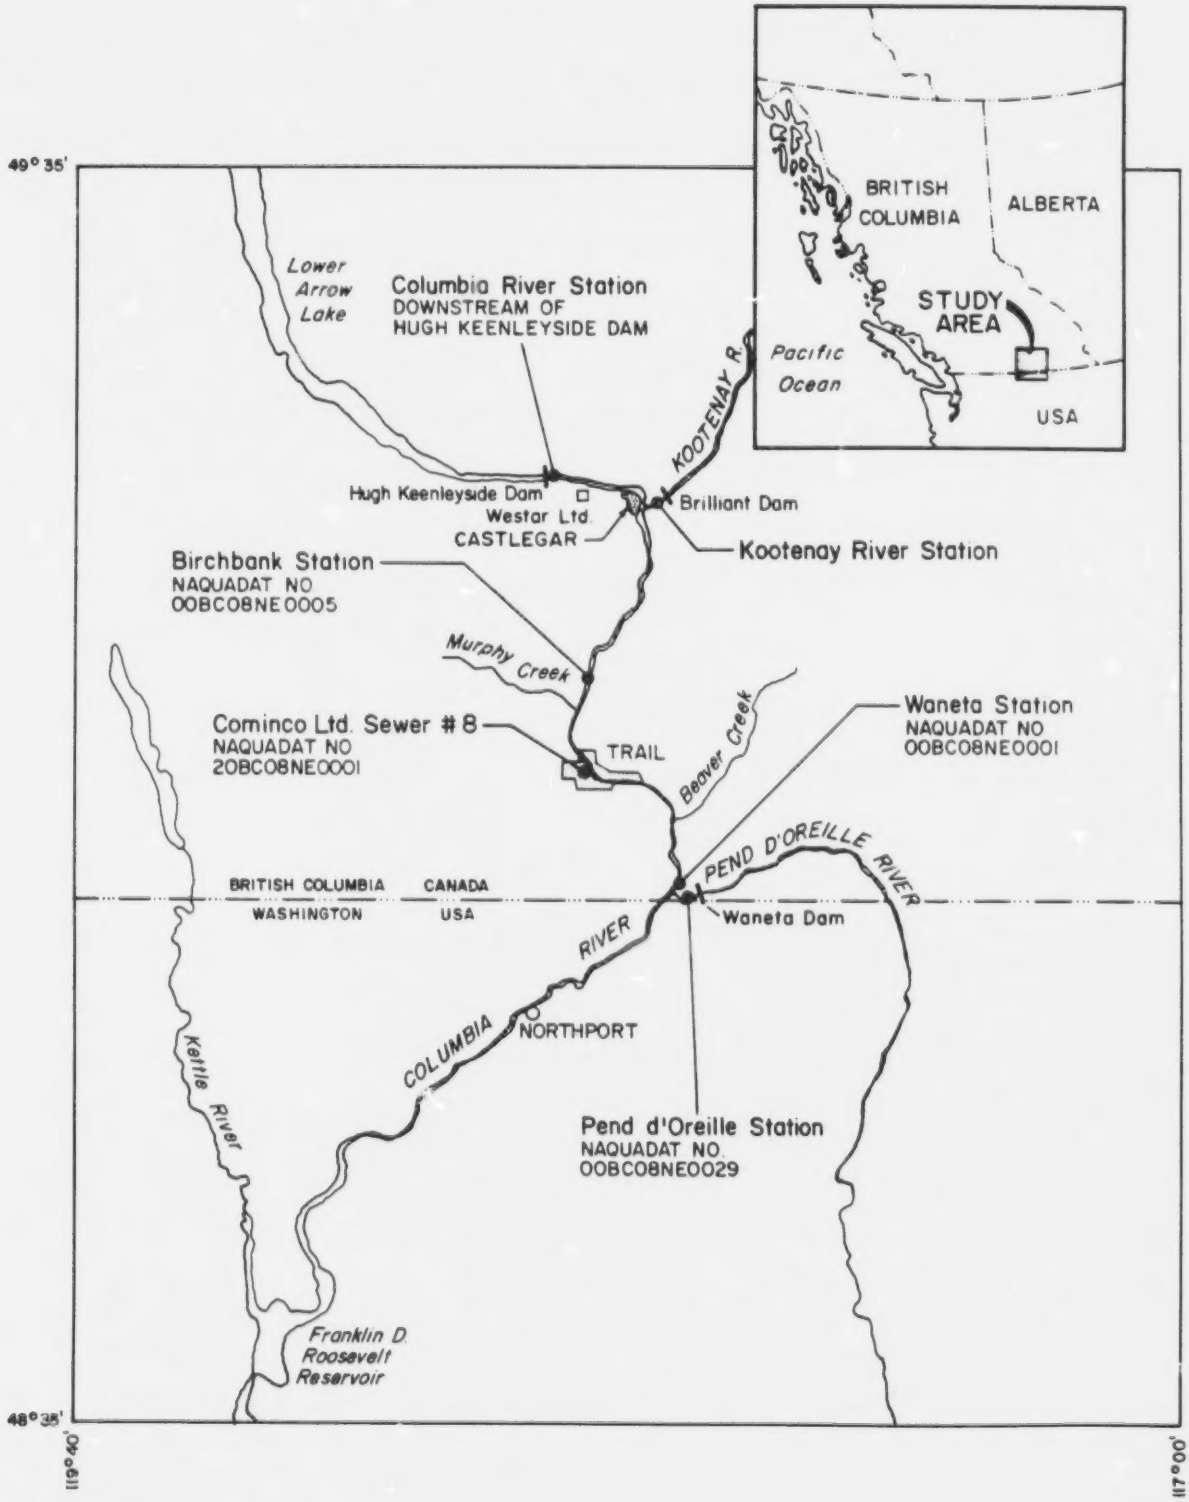

Figure 1 Sampling station locations and NAQUADAT station numbers in the Columbia River Basin, British Columbia

downstream of the Hugh Keenleyside Dam. These upstream sites were sampled to trace the source of elevated metals and nutrient concentrations measured at Birchbank in July 1980.

V. METHODS

A. Sampling Dates

Table 1 presents the sampling dates, sites and types of samples collected.

B. Chemical Methods

1. Field Sampling

Samples for determination of nutrients, metals, and major ions were collected, filtered and/or preserved in the field, and returned to Vancouver for analysis within 30 hours. Usually three replicates were collected. Samples were gathered by dipping appropriate collecting bottles at a wadable distance from the left (east) bank at the Waneta station and from the right (west) bank at the Birchbank station. Samples were collected in a similar fashion from the right (north) bank at the Pend d'Oreille station, from the left (south) bank at the Kootenay River station and from the right (south) bank at the station downstream of the Hugh Keenleyside Dam.

At Cominco, samples were dispensed into the appropriate sample bottles from a 2-L teflon bottle that had been lowered into sewer #8. The teflon bottle was held in a sampling iron (see Inland Waters Directorate, 1983b).

[1] Chemical measurements that were made on this date are reported in Sheehan and Lamb (in prep.).

Details of sampling procedures for specific parameters are summarized in Table 2.

2. Laboratory Analytical Methods

Analyses for the concentrations of chemicals in water were performed at the Water Quality Laboratory in Vancouver according to methods described in the NAQUADAT Dictionary (Inland Waters Directorate, Water Quality Branch, 1983a) and the Analytical Methods Manual (Inland Waters Directorate, Water Quality Branch, 1979). All analyses used, with their identifying NAQUADAT code numbers and limits of detection, are listed in Table 3.

C. Biological Methods

1. Phytoplankton

Phytoplankton were collected by filling three 200-ml bottles with water from just below the water's surface at a wadable distance from the river bank. The samples were preserved with Lugol's solution. When collected with samples for chemical analyses, they were collected at the same locations.

The phytoplankton were enumerated using the Utermöhl technique (Utermöhl, 1958). Samples were shaken, and, depending on algal density, transferred to 5, 10 or 25 cc settling chambers. The samples were settled and then enumerated using an inverted phase contrast microscope. Microscope transects were examined at 625X

TABLE 2

FIELD SAMPLING PROCEDURES FOR CHEMICAL PARAMETERS

Parameter	Field Procedures and Sample Preservation
Total Phosphorus	Samples were collected in 50-ml sovirel glass bottles. The bakelite caps had teflon liner inserts to prevent phosphate contamination. Samples were packed in ice.
Dissolved Phosphorus and Orthophosphorus	Samples were collected in 100-ml sovirel glass bottles capped with teflon-lined bakelite caps. Each sample was filtered through a 47-mm Millipore HA (0.45µm pore diameter) filter which had been pre-soaked in distilled water. The filtering apparatus consisted of a Sartorius polycarbonate filter holder (47 mm diameter, Model SM 165 11). Positive pressure was provided by a hand pump. The filtrate was collected in a 50-ml sovirel glass bottle and packed in ice.
Nitrate and Nitrite, Ammonia, Total Dissolved Nitrogen, Particulate Carbon, Particulate Nitrogen	Samples were collected in 1-L polyethylene bottles. Each sample was filtered within 3 hours through a Whatman GF/F glass fibre filter which had been pre-cooked for 6 hours at 460 C. The filtering apparatus consisted of a glass filter holder coupled to a 1-L erlenmeyer flask, both of which had been prewashed in HCl. The vacuum was provided by a hand pump. The filtrate was collected in a 250-ml polyethylene bottle and packed in ice. The filter was transferred to a petri dish and placed in a cooler.
Dissolved Inorganic Carbon/ Dissolved Organic Carbon (DIC/DOC)	Samples were collected and filtered as above for the nitrogen samples. Samples were placed into 100-ml polyethylene bottles and packed in ice.
Total Inorganic Carbon/ Total Organic Carbon (TIC/TOC)	Samples were collected in 100-ml polyethylene bottles and packed in ice.
Total and extractable metals (Cd, Cu, Fe, Mn, Ni, Pb, Zn)	Samples were collected in 500-ml polyethylene bottles which had been pre-washed in chromic acid cleaning solution.* One millilitre of HNO_3 was added to each bottle no more than 2 hours after collection.

TABLE 2 (Continued)

Parameter	Field Procedures and Sample Preservation
Dissolved metals (Cd, Cu, Fe, Mn, Ni, Pb, Zn)	Samples were collected in 1-L polyethylene bottles. Each sample was filtered through a Millipore HA filter which had been pre-soaked in 0.25% HNO_3 for a minimum of 12 hours. The filtering apparatus consisted of a glass filter holder coupled to a 1-L erlenmeyer flask, both of which had been pre-washed in chromic acid cleaning solution.* The vacuum was provided by a handpump. The filtrate was collected in a 500-ml polyethylene bottle, and 1 ml of HNO_3 was added. A new filter was used for each sample.
Total, Extractable and Dissolved Cr	Samples were collected and filtered (for dissolved Cr) using the same procedures as were used above for the metals samples. The samples were placed into 500-ml polyethylene bottles which had been pre-washed with nitric acid.
Extractable Hg	Samples were collected in 100-ml teflon bottles which had been pre-washed with chromic acid cleaning solution.* Two millilitres of preservative (a solution of 50% HNO_3 and 2.5% $K_2Cr_2O_7$) was added to each bottle no more than 2 hours after collection.
Extractable As, Se	Samples were collected in 100-ml polyethylene bottles which were pre-washed in chromic acid cleaning solution.* The samples were packed in ice.
Major Ions, Residues Physical Parameters	Two 1-L polyethylene bottles were filled with sample water. In the laboratory, aliquots were taken for analyses.

*Chromic acid cleaning solution: Approximately 700 g of sodium dichromate ($Na_2Cr_2O_7$) was added to 8-L of distilled water. Then 4 X 2 1/2-L or 4 winchesters of technical or reagent grade sulphuric acid was stirred into solution.

TABLE 3

NAQUADAT CODE NUMBERS AND LIMITS OF DETECTION FOR THE CHEMICAL PARAMETERS MEASURED IN THE FIELD AND IN THE LABORATORY

Parameter	NAQUADAT Number	Detection Limit
Colour	02011	5.0 Relative units
Specific Conductance	02041	0.2 µ sie/cm
Water Temperature (Lab)	02061	
Water Temperature (Field)	02061	
Turbidity	02073	0 jtu
Total Organic Carbon	06001	Variable
Total Inorganic Carbon	06051	1.0 mg/L
Dissolved Organic Carbon	06101	0.5 mg/L
Dissolved Inorganic Carbon	06151	0.5 mg/L
Particulate Carbon	06903	Variable
NO_3/NO_2 (dissolved)	07110	0.002 mg/L
Ammonia (dissolved)	07557	0.002 mg/L
Total Dissolved Nitrogen (unfiltered)	07651	0.010 mg/L
Total Dissolved Nitrogen (filtered)	07655	0.010 mg/L
Particulate Nitrogen	07903	Variable
Fluoride (dissolved)	09106	0.050 mg/L
Alkalinity (total)	10101	0.5 mg/L $CaCO_3$
Alkalinity (phenolphthalein)	10151	0.5[1] mg/L $CaCO_3$
Acidity	10251	0.5 mg/L $CaCO_3$
pH (Lab)	10301	
Nonfilterable residue	10401	10.0 mg/L
Filterable residue	10451	10.0 mg/L
Nonfilterable residue (fixed)	10501	10.0 mg/L
Filterable residue (fixed)	10551	10.0 mg/L
Hardness (total)	10603	0.5 mg/L $CaCO_3$

[1]This limit of detection applies at pH greater than 8.3. At lower pH phenolphthalein alkalinity = 0

TABLE 3 (Continued)

Parameter	NAQUADAT Number	Detection Limit
Sodium (dissolved)	11103	0.2 mg/L
Magnesium (dissolved)	12101	Calculated
Silica (reactive)	14105	0.2 mg/L
Phosphorus (dissolved)	15102	0.002 mg/L[2]

Lead (extractable)	82302	0.001 mg/L

[3] This parameter was measured in laboratory samples only.

magnification and all phytoplankton were identified and counted until a minimum of 100 cells of the dominant species and at least 300 cells in total were counted.

Filamentous species were enumerated as length of filament. Colonies of small cells were recorded as single cells. Species too small to be identified at a magnification of 625X were identified using phase contrast at 1250X magnification but enumerated at 625X magnification. Because high magnifications can produce errors in the counts of large phytoplankton species, the sample was re-examined at 200X magnification and only large phytoplankton were counted. Only live cells (ie., cells with chloroplasts) were counted. Microscopic counts were converted to cells/ml by the following calculation:

$$\text{cells/ml} = \frac{\text{(cells counted) x (settling area of chamber)}}{\text{(chamber volume) x (area of transects counted)}}$$

Planktonic diatoms in the samples were identified using the reference works of Patrick and Reimer (1966-1975), Cleve-Euler (1951-1955), Hustedt (1930, 1930-1966), Huber Pestalozzi (1942), Sreenivasa and Duthie (1973), and Weber (1966). The species classification scheme of Van Landingham (1967-1979) was followed for diatoms. The works of Bourrelly (1966, 1968, 1970), Prescott (1962) and Huber-Pestalozzi (1938-1972) were used to identify algae from other classes.

2. Periphyton

Periphytic algae were collected for the purpose of determining the dominant species present and not for the estimation of biomass per area of substrate. Algae were removed from rock substrates with a toothbrush or razor blade. The samples were preserved with Lugol's solution.

a. Total Algal Abundance

Each sample bottle was shaken to distribute the algae evenly in the sample. A subsample was transferred to a 5 or 10 ml settling chamber. The algae were settled and then examined with an inverted microscope at 625X or 200X magnification. The percent abundance (by volume) of each algal division was estimated in ten random fields. Non-diatom species abundances were estimated and the species were identified using Prescott (1962), Bourrelly (1966, 1968, 1970) and Huber-Pestalozzi (1938-1972).

b. Diatom Abundance

A subsample of the periphyton sample was prepared for diatom analysis. Prior to 1982, these sub-samples were cleaned in nitric acid as described in Patrick and Reimer (1966-1975). In 1982, samples were cleaned with sulphuric acid, potassium permanganate and oxalic acid as described in Hasle and Fryxell (1970). Following the cleaning, an aliquot was first diluted with distilled water and then poured into an

evaporation dish designed to support four circular coverslips (Battarbee, 1973). The liquid in the dish was allowed to evaporate. When dry, the coverslips were removed and mounted onto slides with Hyrax mounting media (refractive index 1.63). One slide from each sample was examined.

Microscope transects were examined using a phase contrast microscope at 1000X magnification and all diatoms in the sample were identified and counted until a minimum of 100 frustules of the dominant species were enumerated and at least 300 frustules in total were counted. Because this high magnification can produce errors in the counts of large diatoms the sample was re-examined at 200X magnification and only the large diatoms counted. Since the samples were not collected quantitatively, counts are tabulated in intervals of percent abundance of sample observed (i.e. <10%, 10-50%, >50%), rather than as absolute density per area of substrate.

The same keys were used to identify periphyton as were used for phytoplankton.

3. Algal Assays

The algal assays were conducted following the procedure of Miller et al. (1978) with some modifications.

A unialgal but xenic culture of Selenastrum capricornutum was obtained from the United States Environmental Protection Agency,

Corvallis, Oregon. The culture was grown in AAP medium (Miller et al., 1978) and harvested for algal assays when at late logarithmic or early stationary phase of growth.

In preparation for an algal assay, all glassware was washed with low-phosphate detergent in hot water and rinsed 3 times with distilled water. After that, the glassware was soaked in 10% HCl, rinsed in a saturated Na_2CO_3 solution, and then rinsed 10 times with distilled water. Finally, the glassware was dried in an oven at 50-65 C and autoclaved. Polycarbonate flasks were soaked in 10% HNO_3 instead of 10% HCl. Polycarbonate flasks were used in some bioassays as a control to check on possible leaching of metals from the walls of glass flasks (Miller et al., 1975).

Membrane filters used for filtering sample water and nutrient solutions were first soaked overnight in 0.2% HNO_3, then rinsed and soaked several times with distilled water. Prior to autoclaving, one litre of distilled water was passed through each filter.

a. Sample Collection and Preparation

A flowchart of events from sample collection to the termination of the algal assay is presented in Figure 2.

Water samples were collected in 1-L acid-washed teflon bottles from the same locations as the samples for chemical

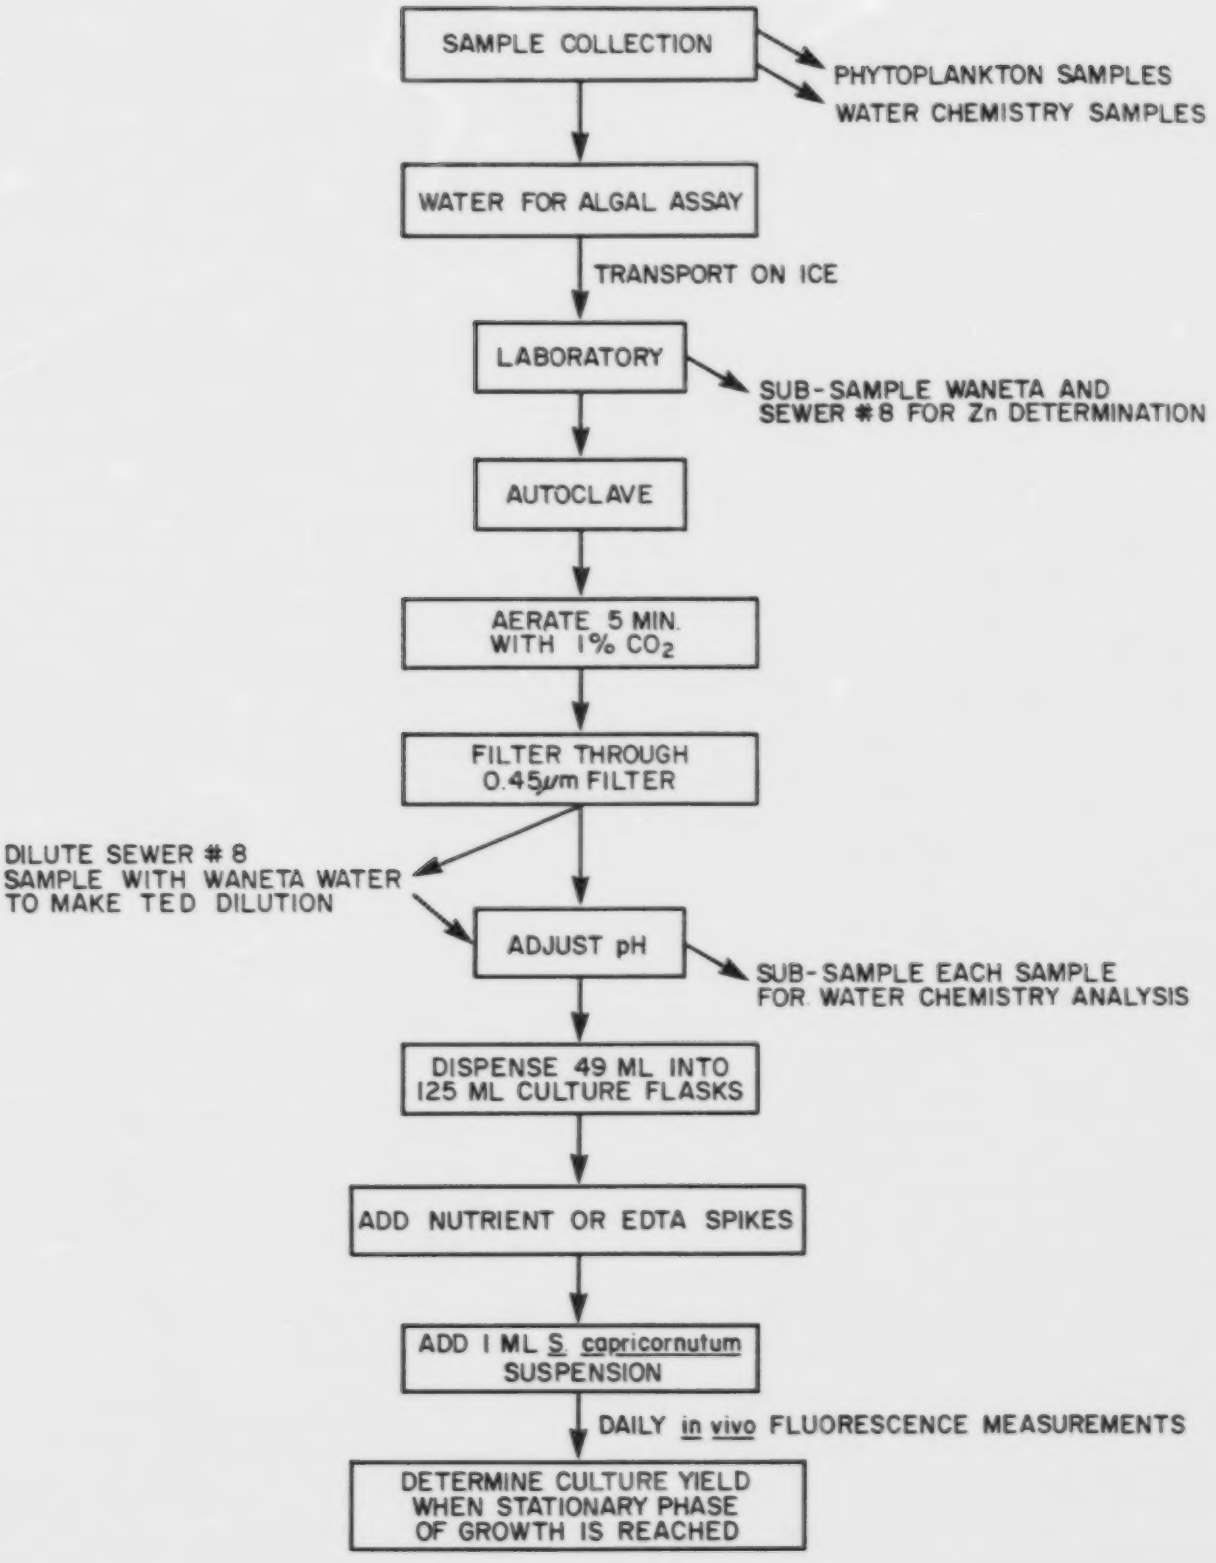

Figure 2 Flowchart outlining the events from water sample collection to the termination of algal assay

and algal species composition analyses were collected. The bottles were immediately packed in ice. The samples were delivered to the laboratory within 30 hours.

At the laboratory, samples were autoclaved (30 minutes per litre of water at 121 C, 1.1 kg/cm^2), aerated with 1% CO_2 and then filtered through Millipore HA membrane filters.

The pH was adjusted to 7.0 $\pm$ 0.5 with 0.1 N NaOH or HCl. The pH of samples collected in August and September of 1982 was adjusted to 8.0 $\pm$ 0.5 to more closely simulate the natural pH (8.0-8.1) of the water.

1. TED sample preparation

   The TED (Total Effluent Dilution) sample designates the dilution of Cominco sewer #8 effluent with Waneta water to simulate a Waneta sample with high concentrations of metals.

   Subsamples of Waneta and sewer #8 water were distributed to appropriate sample bottles immediately when the samples arrived at the laboratory. These subsamples were analysed for dissolved and/or extractable zinc concentration. Zinc was the trace metal usually measured in the highest concentration in the Cominco effluent.

   The results of the zinc analyses were then used to

calculate the volume of sewer #8 water required to increase the zinc concentration of Waneta water to the appropriate level (usually 70µg Zn/L). Previous data showed that zinc concentrations at Waneta frequently reached or exceeded this level. The addition was made after both samples had been autoclaved, aerated with CO_2, and filtered. The pH was adjusted to pH 7 or 8 as described above in Section 3a after the dilution was made. The name of the sample refers to the final dissolved zinc concentration of the water. For example, TED-70 µg Zn/L has a concentration of 70 µg Zn/L.

b. Assay Procedure

The prepared sample water was distributed in 49-ml aliquots to 125-ml erlenmeyer flasks. Some flasks were then spiked with 10 µl of filter-sterilized nutrient and/or EDTA and/or iron solution(s). The trace metal solution was added as a 50 µl spike. Table 4 presents the composition of spike solutions and Table 5 lists all the spikes and combinations of spikes used. Unspiked sample water was referred to as the control, and spiked samples were named control + spike. All treatments were conducted in replicates of 3 or 5.

After the addition of spikes, 1 ml of algal suspension was dispensed to each flask. This resulted in a cell density of

TABLE 4

COMPOSITION OF NUTRIENT AND EDTA SPIKE SOLUTIONS AND THE FINAL CONCENTRATION OF THE SPIKES IN ALGAL ASSAY SAMPLES

Spike	Composition of Spike Stock Solution	Final Concentration of Spike in 50 ml[1] Algal Assay Sample
Phosphorus	0.250g P/L as K_2HPO_4	0.05 mg P/L
Nitrogen	5.000g N/L as $NaNO_3$	1.00 mg N/L
EDTA Chelator	5.000g EDTA/L as Disodium (Ethylenedinitrilo) tetraacetate	1.00 mg EDTA/L
Iron	1.000g Fe/L as $FeCl_3$	0.200 mg Fe/L
Trace Metals	Micronutrient stock solution in Miller et al., 1978:	Trace Metals Solution:
	32.460 mg B/L as H_3BO_3	32.460 µg B/L
	115.374 mg Mn/L as $MnCl_2 \cdot 4H_2O$	115.374 µg Mn/L
	1.570 mg Zn/L as $Zn\ Cl_2$	1.570 µg Zn/L
	0.354 mg Co/L as $CoCl_2 \cdot 6H_2O$	0.354 µg Co/L
	0.004 mg Cu/L as $CuCl_2 \cdot 2H_2O$	0.004 µg Cu/L
	2.878 mg Mo/L as $Na_2MoO_4 \cdot 2H_2O$	2.878 µg Mo/L
	33.051 mg Fe/L as $Fe\ Cl_3 \cdot 6H_2O$	33.051 µg Fe/L
	300.000 mg $Na_2EDTA \cdot 2H_2O$/L	300.000 µg $Na_2EDTA \cdot 2H_2O$

[1] 49 ml sample water + 1 ml algal inoculum

*Refer to Table 2 for the concentrations and identity of the trace metals

approximately 1000 cells/ml. The flasks were plugged with sterile foam plugs (Identi-plugs, Jaece Industries Inc.).

The cultures were incubated at 24 $\pm$ 2 C and continuously illuminated at 4306 $\pm$ 10% lm/m^2 (400 ft-c; lm=lumens) in a Lab-line Environ 3597 environmental chamber. Illumination was provided by Vita-Lite (Duro-Test Corp.) fluorescent tubes. The flasks were continuously shaken at 100 rpm.

The cultures were monitored daily by measuring the in vivo fluorescence with a Turner Fluorometer. The culture was shaken and a sub-sample was poured into a sterile cuvette. The fluorescence reading was measured and the sample was returned to the original culture. After 14 days or when the stationary phase of growth was reached (ie.: when the daily increase in chlorophyll content as measured in relative fluorescence units was $\leq$5%), the cell density was determined and the algal assay was terminated. For algal assays conducted prior to June 1982, the final cell density was determined using a haemocytometer. For algal assays conducted in June 1982 to September 1982, cell density was measured with a Model ZB1 Coulter Electronic Particle Counter. Isoton II electrolyte solution (Coulter Electronics) was used to dilute the culture for Coulter Counter measurements.

For algal assays conducted in June, August, and September of 1982, the mean cell volume of each culture was determined with the Coulter Model MHR. The Coulter Counter was calibrated with 4.91-µm latex microspheres. For these three algal assays, it was possible to calculate the dry weight yield of S. capricornutum in each culture by the following calculation (Miller et al., 1978):

$$\text{mg dry weight} = \text{cell counts (cells/ml)} \times \text{MCV} \times 3.61 \times 10^{-7}$$

where, MCV = mean cell volume (μm^3/cell)
3.61×10^{-7} = calculated dry wt ($\mu g/\mu m^3$) of S. capricornutum, as determined below.

c. Determination of Dry Weight per Volume S. capricornutum

Two cultures of S. capricornutum were grown in AAP medium to the late logarithmic phase of growth. The cultures were shaken and the cell densities (cells/ml) and mean cell volumes (μm^3/cell) were determined using the Coulter Counter.

Measured volumes of each culture were filtered onto pre-dried and pre-weighed Millipore HA filters. These filters were then dried at 60-65 C in an oven, cooled in a dessicator for 24 hours, and weighed. The following equation was used to calculate the dry weight of S. capricornutum per volume of algae ($\mu g/\mu m^3$):

$$\text{dry wt. } (\mu g/\mu m^3) = \frac{DW}{VF \times CD \times MCV}$$

where, DW = dry weight of algae on filter (µg)
VF = volume filtered (ml)
CD = cell density (cells/ml)
MCV = mean cell volume (μm^3/cell)

d. Concentrations of Metals and Nutrients in the Prepared Sample Water

For assays conducted prior to 1982, subsamples for chemical analysis were removed after the filtration step. For assays conducted in 1982, subsamples were removed from each sample just prior to their distribution into culture flasks (i.e., after pH adjustment of sample water). These subsamples were analysed for the following: orthophosphate, total dissolved phosphorus, nitrate/nitrite, ammonia, total dissolved nitrogen, dissolved Zn, Cu, Fe, Mn, Cd, Pb, Ni and Hg. The procedures used for the analyses are described in the chemical methods section.

In February 1980, March 1980, and June 1982, the concentrations of metals and nutrients in the water were measured at various stages of the laboratory procedures to test for possible changes at each stage. Samples were taken:

- before autoclaving
- after filtration without autoclaving
- after autoclaving
- after autoclaving and CO_2 aeration
- after autoclaving and filtration without CO_2 aeration
- after autoclaving, CO_2 aeration, and filtration
- after autoclaving, CO_2 aeration, filtration, and pH adjustment.

VI. RESULTS

A. Algal Assay Results

The algal assay data are presented in chronological order. The algal growth data for assays conducted in February 1980 and March 1980 are not presented in this report because the algal assay techniques had not been perfected and the growth data were suspect. Data on the concentrations of chemicals in the water, however, are presented. These chemical data are included because these data are used to evaluate the effect of the pre-assay treatment on the concentrations of chemicals in the water.

For each assay, the data are presented in the following order:

1) Table on the concentrations of chemcials in the water and Cominco effluent (this water has not been treated at the laboratory).
2) Table on the concentrations of chemicals in the water and Cominco effluent at various stages or one stage of pre-assay laboratory preparation.
3) Table on the daily *in vivo* chlorophyll *a* readings (expressed as relative fluorometer units).
4) Figures graphing the algal growth as daily *in vivo* chlorophyll *a* readings. These graphs are based on the data presented in the table described in item (3), above.
5) Table on the final yield of each algal assay treatment.

The analytical procedures and associated NAQUADAT method number for the parameters listed in the report are consistent for each parameter. For example, the orthophosphorus analytical procedure identified as 15256 (phosphorus dissolved ortho PO4) for the water samples at Birchbank and Waneta on February 14, 1980 (Table 6) is the same analytical procedure used for the analysis of orthophosphorus in Tables 7a and 7b.

When the concentration of a chemical was recorded as less than detection limit (L), the limit of detection was used as the value in the calculation of mean and standard deviation. In the tables, S.D. = standard deviation; G.F. = geometric factor or standard deviation of the geometric mean.

TABLE 6

CONCENTRATIONS OF CHEMICALS IN THE COLUMBIA RIVER ON FEBRUARY 14, 1980. CONCENTRATIONS OF ALL CHEMICALS EXCEPT HG ARE REPORTED IN mg/L; HG IS IN µg/L. PARAMETERS ARE LISTED UNDER THEIR NAQUADAT CODE NUMBERS AS SUMMARIZED IN TABLE 3

*denotes that the statistics are based on some L (less than detection limit) values.

TABLE 8

CONCENTRATIONS OF CHEMICALS IN THE COLUMBIA RIVER ON MARCH 26, 1980. CONCENTRATIONS OF ALL CHEMICALS EXCEPT HG ARE REPORTED IN mg/L; HG IS IN µg/L. PARAMETERS ARE LISTED UNDER THEIR NAQUADAT CODE NUMBERS AS SUMMARIZED IN TABLE 3

*denotes that the statistics are based on some L (less than detection limit) values.

TABLE 14

CONCENTRATIONS OF CHEMICALS IN THE COLUMBIA RIVER ON AUGUST 11, 1980. CONCENTRATIONS OF ALL CHEMICALS EXCEPT HG ARE REPORTED IN mg/L; HG IS IN µg/L. PARAMETERS ARE LISTED UNDER THEIR NAQUADAT CODE NUMBERS AS SUMMARIZED IN TABLE 3

*denotes that the statistics are based on some L (less than detection limit) values.

TABLE 26

CONCENTRATIONS OF CHEMICALS IN THE COLUMBIA RIVER ON FEBRUARY 17, 1981. CONCENTRATIONS OF ALL CHEMICALS EXCEPT HG ARE REPORTED IN mg/L; HG IS IN µg/L. PARAMETERS ARE LISTED UNDER THEIR NAQUADAT CODE NUMBERS AS SUMMARIZED IN TABLE 3

*denotes that the statistics are based on some L (less than detection limit) values.

ALGAL GROWTH INDICATED BY *IN VIVO* CHLOROPHYLL *A*

(MEASURED IN RELATIVE FLUOROMETER UNITS)

FOR THE FEBRUARY 1981 ALGAL ASSAY.

FOR ALL TREATMENTS, EXCEPT CONTROL + 200µg Fe/L FROM BIRCHBANK, THE POINTS PLOTTED ARE THE MEANS OF 5 REPLICATES. THE POINTS PLOTTED FOR CONTROL + 200µg Fe/L FROM BIRCHBANK ARE THE MEANS OF 3 REPLICATES

The readings used for these graphs are presented in Table 28

TABLE 33

FINAL YIELD OF EACH ALGAL ASSAY TREATMENT FOR THE JUNE 1982 ASSAY.

THE YIELDS ARE EXPRESSED AS CELLS/ML AND MG DRY WT/L.

MEAN CELL VOLUME IS EXPRESSED AS UM^3/CELL.

THE YIELDS WERE DETERMINED WITH THE COULTER COUNTER.

June 23 - July 7, 1982 Algal Assay

TABLE 37

FINAL YIELD OF EACH ALGAL ASSAY TREATMENT FOR THE AUGUST 1982 ASSAY.

THE YIELDS ARE EXPRESSED AS CELLS/ML AND MG DRY WT/L.

MEAN CELL VOLUME IS EXPRESSED AS UM^3/CELL.

THE YIELDS WERE DETERMINED WITH THE COULTER COUNTER.

August 19 - September 5, 1982 Algal Assay

Birchbank

TABLE 38

CONCENTRATIONS OF CHEMICALS IN THE COLUMBIA RIVER ON SEPTEMBER 28, 1982. CONCENTRATIONS OF ALL CHEMICALS EXCEPT HG ARE REPORTED IN mg/L; HG IS IN µg/L. PARAMETERS ARE LISTED UNDER THEIR NAQUADAT CODE NUMBERS AS SUMMARIZED IN TABLE 3

*denotes that the statistics are based on some L (less than detection limit) values.

TABLE 41

FINAL YIELD OF EACH ALGAL ASSAY TREATMENT
FOR THE SEPTEMBER 1982 ASSAY. THE YIELDS ARE EXPRESSED
AS CELLS/ML AND MG DRY WT/L.
MEAN CELL VOLUME IS EXPRESSED AS UM^3/CELL.
THE YIELDS WERE DETERMINED WITH THE COULTER COUNTER.

September 30 - October 26, 1982 Algal Assay

Table 51a

Concentrations of phytoplankton species (cells/ml) collected from the Kootenay River on August 11, 1980. Concentrations of filamentous species (indicated by *) are expressed as mm/ml. Filamentous species are not included in total count of cells.

Species	Replicates		
Chrysophyta			
Class Bacillariophyceae			
Achnanthes minutissima	0	0	3
Asterionella formosa	61	33	135
Cyclotella sp.	0	8	8
Diatoma elongatum	11	14	33
Diploneis decipiens	0	0	3
Fragilaria construens var. binodis	44	0	0
Fragilaria crotonensis	1154	182	328
Fragilaria vaucheriae	39	3	0
Navicula sp.	0	11	0
Nitzschia palea	0	0	6
Rhizosolenia eriensis	0	11	0
Synedra acus var. radians	6	6	6
Synedra ulna	50	25	11
Tabellaria fenestrata	33	8	11
Non-Diatom Chrysophyta			
Dinobryon sertularia	0	33	0
Mallomonas pseudocoronata	0	8	0
Ochromonas sp.	132	232	400
Chlorophyta			
Ankistrodesmus falcatus	77	44	28
Cosmarium sp.	0	6	6
Elakatothrix gelatinosa	0	0	6
Gemellicystis neglecta	0	22	0
Cryptophyta			
Chroomonas sp.	166	359	582
Cryptomonas sp.	17	22	6
Cyanophyta			
Oscillatoria planctonica*	1766	386	911
Pyrrhophyta			
Peridinium sp.	0	3	0
Total Count	1788	1029	1570

Table 51b

Concentrations of phytoplankton species (cells/ml) collected from the Columbia River downstream from the Hugh Keenleyside Dam on August 11, 1980.

Species	Replicates		
Chrysophyta			
Class Bacillariophyceae			
Achnanthes minutissima	3	0	2
Asterionella formosa	8	44	35
Cyclotella sp.	3	3	5
Cymbella ventricosa	0	0	<1
Diploneis decipiens	<1	0	0
Fragilaria construens var. binodis	49	6	9
Fragilaria crotonensis	38	29	33
Fragilaria vaucheriae	0	1	0
Navicula sp.	0	4	0
Nitzschia acicularis	<1	0	0
Synedra ulna	1	0	2
Tabellaria fenestrata	2	0	0
Non-Diatom Chrysophyta			
Dinobryon sertularia	8	4	17
Ochromonas sp.	0	9	0
Chlorophyta			
Elakatothrix gelatinosa	<1	0	0
Cryptophyta			
Chroomonas sp.	12	21	51
Cryptomonas sp.	17	2	4
Pyrrhophyta			
Peridinium sp.	2	7	8
Total Count	145	129	165
